Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q308. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q309. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q310. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q311. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q312. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q313. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q314. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q315. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q316. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q317. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q318. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q319. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q320. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q321. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q322. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q323. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q324. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q325. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q326. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q327. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q328. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q329. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q330. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q331. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q332. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q333. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q334. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q335. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q336. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q337. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q338. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q339. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q340. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q341. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q342. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q343. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q344. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q345. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q346. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q347. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q348. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q349. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q350. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q351. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q352. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q353. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q354. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q355. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q356. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q357. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q358. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q359. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q360. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q361. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q362. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q363. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q364. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q365. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q366. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q367. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q368. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q369. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Topic: Geniculate Ganglion

Q384. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q385. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q386. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q387. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q388. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q389. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q390. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q391. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q392. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q393. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q394. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q395. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q396. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q397. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q398. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q399. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q400. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q401. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q402. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q403. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q404. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q405. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q406. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q407. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q408. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q409. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q410. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q411. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q422. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q423. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q424. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q425. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q426. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q427. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q428. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q429. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q430. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q431. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q432. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q433. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q434. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q435. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q436. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q437. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q438. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q439. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q440. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q441. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q442. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q443. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q444. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q445. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q446. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q447. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q448. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q449. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q450. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q451. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q452. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q453. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q454. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q464. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q465. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q466. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q467. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q468. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q469. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q470. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q471. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q472. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q473. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q474. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q475. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q476. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q477. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q478. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q479. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q480. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q481. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q482. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q483. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q484. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q485. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q486. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q487. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q488. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q489. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q490. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Topic: Functional Components

Q491. Describe the four functional components of the facial nerve. What are the nuclei of origin for each component?

Answer: The facial nerve has four functional components: 1) Branchial motor (SVE): From facial motor nucleus in pons. Innervates muscles of facial expression, stapedius, stylohyoid, posterior digastric. 2) Parasympathetic (GVE): From superior salivatory nucleus. Innervates lacrimal, submandibular, and sublingual glands. 3) Special sensory (SVA): Taste from anterior 2/3 of tongue. Cell bodies in geniculate ganglion, terminate in solitary nucleus. 4) General sensory (GSA): Small area of skin around external ear. Cell bodies in geniculate ganglion, terminate in spinal trigeminal nucleus. Clinical: This complexity explains the diverse symptoms in facial nerve lesions.

Topic: Intracranial Course

Q492. Describe the intracranial course of the facial nerve from brainstem to internal acoustic meatus.

Answer: Intracranial course: The facial nerve emerges from the pontomedullary junction as two roots: 1) Motor root: Large, medial. 2) Nervus intermedius: Smaller, lateral, carries sensory and parasympathetic fibers. Both roots travel with CN VIII through the cerebellopontine angle cistern and enter the internal acoustic meatus. In the meatus, the motor root lies in a groove on CN VIII, and the nervus intermedius lies between them. They travel 1cm laterally within the meatus before entering the facial canal. Clinical: Acoustic neuroma (vestibular schwannoma) in the CPA cistern commonly compresses CN VII.

Topic: Intratemporal Segments

Q493. Name the three segments of the facial nerve within the temporal bone. What branches arise from each segment?

Answer: Three segments in temporal bone: 1) Labyrinthine segment: Shortest, narrowest, from IAC to geniculate ganglion. No branches. Site of compression in Bell's palsy. 2) Tympanic segment: From geniculate ganglion to pyramidal eminence, runs in medial wall of middle ear. Branches: Greater petrosal nerve (from geniculate), nerve to stapedius. 3) Mastoid segment: From pyramidal eminence to stylomastoid foramen. Branches: Chorda tympani, nerve to stapedius (if not given earlier). The nerve makes two turns: First genu at geniculate ganglion, second genu at pyramidal eminence. Clinical: Surgical landmarks during mastoidectomy.

Topic: Geniculate Ganglion

Q494. What is the geniculate ganglion? What branches arise from it and what do they carry?

Answer: The geniculate ganglion is the sensory ganglion of CN VII, located at the first genu in the temporal bone. It contains cell bodies for: 1) Taste from anterior 2/3 of tongue via chorda tympani. 2) General sensation from external ear. Branches from geniculate ganglion: 1) Greater petrosal nerve: Carries preganglionic parasympathetic to pterygopalatine ganglion for lacrimal and nasal glands. 2) Lesser petrosal nerve: Inconstant, sometimes carries parasympathetic to otic ganglion. 3) External petrosal nerve: Small, sympathetic. Clinical: Herpes zoster infection of the geniculate ganglion causes Ramsay Hunt syndrome.

Topic: Chorda Tympani

Q495. Describe the course of the chorda tympani from its origin to its termination. What two functions does it have?

Answer: Chorda tympani: Origin - From facial nerve 6mm above stylomastoid foramen in the mastoid segment. Course: Runs superiorly through posterior canaliculus to enter middle ear cavity. Passes medial to tympanic membrane between malleus and incus. Exits via petrotympanic fissure to enter infratemporal fossa. Joins lingual nerve (V3) at an acute angle and travels with it to the tongue and submandibular ganglion. Two functions: 1) Taste from anterior 2/3 of tongue (SVA). 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands (GVE). Clinical: Damaged during middle ear surgery or third molar surgery, causing loss of taste and dry mouth.

Topic: Extracranial Course

Q496. Where does the facial nerve exit the skull? Describe its course after exiting to enter the parotid gland.

Answer: The facial nerve exits the skull through the stylomastoid foramen, located between the styloid and mastoid processes. After exiting: 1) Gives off posterior auricular nerve (to occipitalis and auricular muscles), nerve to posterior digastric, and nerve to stylohyoid. 2) Enters the parotid gland through its posteromedial surface and passes superficial to the retromandibular vein and external carotid artery. Within the parotid, it divides into temporofacial and cervicofacial divisions at the pes anserinus. These then divide into the five terminal branches. Clinical: The nerve is at risk during parotid surgery. The main trunk is found 1cm inferior and deep to the tragal pointer.

Topic: Five Terminal Branches

Q497. Name the five terminal branches of the facial nerve within the parotid gland. What muscles does each supply?

Answer: Five terminal branches (TO Zanzibar By Motor Car): 1) Temporal: To frontalis, orbicularis oculi (upper), corrugator. 2) Zygomatic: To orbicularis oculi (lower), zygomaticus major/minor. 3) Buccal: To buccinator, orbicularis oris (upper), nasal muscles. 4) Marginal mandibular: To orbicularis oris (lower), depressor anguli oris, depressor labii inferioris, mentalis. 5) Cervical: To platysma. Clinical: Marginal mandibular is most commonly injured during submandibular gland surgery or neck dissection, causing ipsilateral lip droop and inability to depress lower lip. Buccal and zygomatic branches have multiple cross-innervations.

Topic: Bell's Palsy

Q498. What is Bell's palsy? What are the clinical signs and how do you differentiate it from an upper motor neuron lesion?

Answer: Bell's palsy is an acute, idiopathic, unilateral lower motor neuron facial paralysis. Clinical signs: Ipsilateral weakness of all facial muscles (forehead, eye closure, mouth). Other signs: Hyperacusis (stapedius paralysis), loss of taste anterior 2/3 tongue (chorda tympani), decreased lacrimation (greater petrosal), and decreased salivation. Differentiation from UMN lesion (stroke): In Bell's palsy (LMN), the forehead is paralyzed because both sides of the face receive only contralateral cortical input to the upper face. In UMN lesion, the forehead is spared because of bilateral cortical input. Cause: Likely HSV-1 reactivation causing edema and compression in the labyrinthine segment. Treatment: Steroids + antivirals within 72 hours.

Topic: Ramsay Hunt Syndrome

Q499. What is Ramsay Hunt syndrome? Which branch of CN VII is involved and what are the three classic symptoms?

Answer: Ramsay Hunt syndrome is herpes zoster infection of the geniculate ganglion. Branch involved: Sensory and motor fibers of CN VII. Classic triad: 1) Ipsilateral facial paralysis (LMN). 2) Ear pain (otalgia). 3) Vesicular rash in the external auditory canal, auricle, or oral mucosa. Other symptoms: Vertigo, hearing loss, tinnitus (CN VIII involvement), loss of taste. Mechanism: Varicella-zoster virus reactivates in the geniculate ganglion. Clinical: Worse prognosis than Bell's palsy. Only 50% achieve full recovery vs 85% in Bell's. Treatment: High-dose antivirals and steroids. Important to differentiate from Bell's by checking for vesicles.

Topic: Stapedius & Hyperacusis

Q500. Describe the nerve to stapedius and its clinical significance. What happens when it is damaged?

Answer: Nerve to stapedius: Arises from the mastoid segment of CN VII in the facial canal. It innervates the stapedius muscle in the middle ear. The stapedius dampens vibrations of the stapes to protect the inner ear from loud sounds. Clinical significance: Damage to the facial nerve proximal to this branch (e.g., Bell's palsy) causes hyperacusis - painful sensitivity to loud sounds because the stapedius is paralyzed. If the lesion is distal to this branch (e.g., at stylomastoid foramen), hyperacusis is absent. This is used to localize the level of facial nerve lesions. The stapedius reflex is tested during audiometry.

Jaw and Face Anatomy - Part 18

Salivary Glands: Parotid, Submandibular, Sublingual - 500 Questions

Topic: Parotid Gland

Q1. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q2. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q3. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q4. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q5. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q6. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q7. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q8. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q9. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q10. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q11. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q12. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q13. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q14. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q15. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q16. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q17. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q18. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q19. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q20. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q21. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q22. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q23. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q24. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q25. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q26. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q27. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q28. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q29. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q30. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q31. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External

carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q32. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q33. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q34. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q35. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the

tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q36. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q37. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q38. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q39. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or

trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q40. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q41. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q42. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q43. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q44. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q45. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q46. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q47. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q48. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q49. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q50. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q51. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q52. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q53. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q54. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q55. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q56. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q57. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q58. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q59. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q60. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q61. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q62. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q63. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q64. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q65. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q66. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q67. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q68. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q69. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q70. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q71. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q72. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q73. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q74. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q75. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q76. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q77. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q78. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q79. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q80. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q81. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q82. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q83. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q84. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q85. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q86. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q87. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q88. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q89. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q90. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q91. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q92. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q93. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q94. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q95. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q96. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q97. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q98. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q99. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q100. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q101. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q102. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q103. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q104. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q105. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q106. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q107. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q108. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q109. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q110. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q111. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q112. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q113. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q114. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q115. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q116. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q117. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q118. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q119. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q120. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q121. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q122. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q123. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q124. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q125. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q126. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q127. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q128. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q129. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q130. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q131. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q132. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q133. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q134. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q135. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q136. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q137. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q138. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q139. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q140. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q141. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q142. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q143. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q144. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q145. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q146. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q147. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q148. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q149. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q150. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q151. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q152. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q153. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q154. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q155. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q156. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q157. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q158. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q159. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q160. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q161. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q162. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q163. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q164. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q165. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q166. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q167. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q168. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q169. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q170. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q171. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q172. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q173. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q174. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q175. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q176. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q177. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q178. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q179. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q180. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q181. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q182. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q183. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q184. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q185. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q186. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q187. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q188. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q189. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q190. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q191. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q192. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Topic: Frey's Syndrome

Q199. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q200. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q201. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q202. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q203. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q204. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q205. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q206. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q207. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q208. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q209. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q210. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q211. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q212. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q213. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q214. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q215. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q216. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q217. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q218. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q219. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q220. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q221. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q222. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q223. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q224. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q225. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q226. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q227. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q228. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q229. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q230. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q231. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q232. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q233. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q234. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q235. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q236. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q237. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q238. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q239. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q240. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q241. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q242. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q243. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q244. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q245. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q246. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q247. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q248. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q249. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q250. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q251. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q252. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q253. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q254. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q255. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q256. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q257. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q258. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q259. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q260. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q261. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q262. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q263. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q264. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q265. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q266. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q267. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q268. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q269. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q270. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q271. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q272. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q273. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q274. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q275. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Topic: Parotid Innervation

Q283. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q284. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q285. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q286. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q287. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q288. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q289. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q290. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q291. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q292. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q293. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q294. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q295. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q296. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q297. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q298. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q299. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q300. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q301. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q302. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q303. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q304. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q305. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q306. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q307. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q308. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q309. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q310. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q311. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q312. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q313. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q314. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q315. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q316. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q317. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q318. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q319. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q320. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q321. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q322. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q323. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q324. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q325. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q326. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q327. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q328. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q329. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q330. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q331. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q332. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q333. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q334. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q335. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q336. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q337. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q338. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q339. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q340. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q341. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q342. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q343. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q344. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q345. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q346. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q347. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q348. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q349. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q350. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q351. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q352. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q353. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q354. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q355. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q356. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q357. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q358. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q359. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q360. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q361. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q362. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q363. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q364. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q365. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q366. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q367. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q368. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q369. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q370. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q371. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q372. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q373. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q374. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q375. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q376. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q377. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q378. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q379. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q380. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q381. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q382. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q383. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q384. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q385. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q386. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q387. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q388. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q389. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q390. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q391. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q392. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q393. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q394. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q395. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q396. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q397. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q398. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Topic: Frey's Syndrome

Q399. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q400. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q401. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q402. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q403. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q404. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q405. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q406. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q407. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q408. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q409. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q410. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q411. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q412. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q413. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q414. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q415. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q416. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q417. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q418. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q419. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q420. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q421. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q422. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q423. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q424. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q425. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q426. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q427. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q428. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q429. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q430. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q431. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q432. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q433. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q434. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q435. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q436. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q437. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q438. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q439. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q440. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q441. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q442. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Topic: Parotid Innervation

Q443. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q444. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q445. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q446. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q447. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q448. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q449. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q450. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q451. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q452. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q453. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q454. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q455. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q456. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q457. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q458. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q459. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q460. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q461. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q462. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is

palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q463. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q464. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q465. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q466. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both

glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q467. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q468. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q469. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q470. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2)

Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q471. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q472. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q473. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q474. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q475. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q476. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q477. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q478. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q479. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q480. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q481. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Topic: Parotid Innervation

Q483. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q484. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q485. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q486. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q487. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q488. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q489. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q490. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Topic: Parotid Gland

Q491. Describe the location, capsule, and surfaces of the parotid gland. What structures pass through it?

Answer: Parotid gland: Location - Wedge-shaped, between ramus of mandible and mastoid/sternocleidomastoid, from zygomatic arch to angle of mandible. Capsule - Dense fibrous capsule derived from investing layer of deep cervical fascia, forming a false capsule. The true capsule sends septa into the gland. Structures passing through (lateral to medial): 1) Facial nerve (CN VII) and its branches - divides gland into superficial and deep lobes. 2) Retromandibular vein - formed by union of superficial temporal and maxillary veins. 3) External carotid artery - enters inferiorly, gives maxillary and superficial temporal branches. 4) Auriculotemporal nerve (V3). 5) Parotid lymph nodes. Clinical: Parotid tumors are 80% benign, 80% in superficial lobe, 80% are pleomorphic adenoma.

Topic: Stensen's Duct

Q492. Describe the course of the parotid duct (Stensen's duct). What is its surface landmark and clinical significance?

Answer: Parotid duct (Stensen's duct): 5cm long. Course: Emerges from anterior border of gland, runs horizontally over masseter, turns medially at anterior border of masseter to pierce buccinator, and opens into oral vestibule opposite the maxillary second molar crown. Surface landmark: Middle third of a line from tragus to midpoint of upper lip. It runs with the transverse facial artery above and buccal branch of CN VII below. Clinical significance: 1) The duct is palpated/seen when checking for stones or when massaging the gland. 2) It can be cannulated for sialography. 3) Sialolithiasis here causes painful swelling during meals. 4) Fistula can form after trauma.

Topic: Parotid Innervation

Q493. What is the nerve supply of the parotid gland? Describe the pathway of parasympathetic innervation via the otic ganglion.

Answer: Nerve supply of parotid: Parasympathetic (secretomotor) - From inferior salivatory nucleus → CN IX → tympanic branch → tympanic plexus → lesser petrosal nerve → otic ganglion → synapse → auriculotemporal nerve (V3) → parotid. Sympathetic - From superior cervical ganglion → plexus on external carotid → vasoconstriction, reduces secretion. Sensory - Auriculotemporal nerve (V3) and great auricular nerve (C2, C3). Clinical: Gustatory sweating (Frey's syndrome) occurs when parasympathetic fibers regenerate into cutaneous branches after parotidectomy. The gland does not have motor innervation.

Topic: Submandibular Gland

Q494. What are the relations of the submandibular gland? Describe its superficial and deep parts and their relation to the mylohyoid.

Answer: Submandibular gland: Location - In the submandibular triangle, partly under the body of mandible. It has two parts connected around the posterior border of mylohyoid: 1) Superficial part: Larger, lies inferior to mylohyoid in the digastric triangle. Relations: Superiorly - mylohyoid; Laterally - mandible, medial pterygoid, facial artery; Medially - hyoglossus, lingual and hypoglossal nerves. 2) Deep part: Smaller, lies superior to mylohyoid on hyoglossus, in the floor of mouth. The facial artery grooves the posterior and superior surfaces. The gland is enclosed by the investing layer of deep cervical fascia. Clinical: The gland is palpable bimanually and is removed for chronic sialadenitis or tumors.

Topic: Wharton's Duct

Q495. Describe the course of the submandibular duct (Wharton's duct). What is its relation to the lingual nerve?

Answer: Submandibular duct (Wharton's duct): 5cm long. Course: Begins in the deep part of the gland, runs anteriorly between mylohyoid (inferior) and hyoglossus (medial), then between sublingual gland and genioglossus, to open at the sublingual papilla beside the frenulum of the tongue. Relation to lingual nerve: The lingual nerve loops under the duct, passing from lateral to medial. At the posterior border of mylohyoid, the nerve is lateral to the duct. Anteriorly, it crosses below the duct to become medial. Clinical: This crossing is the danger point during stone removal from the duct. The duct is prone to sialolithiasis because secretion is more viscous and the duct runs uphill.

Topic: Submandibular Ganglion

Q496. What is the nerve supply of the submandibular and sublingual glands? Describe the pathway via the submandibular ganglion.

Answer: Nerve supply of submandibular/sublingual glands: Parasympathetic (secretomotor) - From superior salivatory nucleus → CN VII → chorda tympani → joins lingual nerve (V3) → submandibular ganglion (suspended from lingual nerve) → synapse → direct branches to both glands. Sympathetic - From superior cervical ganglion → plexus on facial artery → vasoconstriction, produces viscous saliva. Sensory - Lingual nerve (V3). Clinical: Damage to chorda tympani during third molar surgery or submandibular gland excision causes loss of taste to anterior 2/3 tongue and reduced salivation from these glands, causing xerostomia.

Topic: Sublingual Gland

Q497. Describe the sublingual gland. What are the ducts of Rivinus and the duct of Bartholin?

Answer: Sublingual gland: Smallest major salivary gland, almond-shaped, lies in the sublingual fossa of the mandible, superior to mylohyoid, between the mandible and genioglossus. It is covered only by oral mucosa, causing the sublingual fold. Ducts: 1) Ducts of Rivinus: 8-20 small ducts that open directly onto the sublingual fold. 2) Duct of Bartholin: Larger duct from the posterior part that usually joins the submandibular duct, but may open separately. The gland is mainly mucous. Clinical: Ranula is a mucocele of the sublingual gland that presents as a bluish swelling in the floor of mouth. Plunging ranula extends through mylohyoid into the neck.

Topic: Sialolithiasis

Q498. What is sialolithiasis? Which gland and duct are most commonly affected and why?

Answer: Sialolithiasis is stone formation in a salivary gland or duct. Most commonly affected: Submandibular gland and Wharton's duct (80-90% of cases). Reasons: 1) Secretion is more viscous and alkaline with higher calcium and phosphate. 2) The duct is long, tortuous, and runs uphill against gravity. 3) The orifice is smaller than the duct. Clinical: Painful swelling of the gland during meals (mealtime syndrome) because saliva cannot exit. The stone can be palpated bimanually in the floor of mouth. Treatment: Sialagogues, massage, sialoendoscopy, or surgical removal. Parotid stones are less common (10-20%) because secretion is serous and duct is shorter.

Topic: Frey's Syndrome

Q499. What is Frey's syndrome? What is the mechanism and which gland is involved?

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of the skin over the parotid region during eating. Gland involved: Parotid gland. Mechanism: After parotidectomy or trauma, the postganglionic parasympathetic secretomotor fibers from the otic ganglion that were severed regenerate and aberrantly join the auriculotemporal nerve's cutaneous branches that supply sweat glands. When the patient eats, parasympathetic stimulation for salivation instead causes sweating. Test: Minor's starch-iodine test - paint iodine on skin, dust with starch, patient eats lemon, area turns blue-black. Treatment: Botox injections, topical antiperspirants, or interposition of fascia during surgery.

Topic: Gland Histology

Q500. Describe the histological differences between parotid, submandibular, and sublingual glands. Which produces serous vs mucous secretion?

Answer: Histological differences: 1) Parotid: Purely serous acini. Secretes watery, amylase-rich saliva. Stains dark with H&E.; Most susceptible to mumps virus and Sjögren's syndrome. 2) Submandibular: Mixed but predominantly serous (90% serous, 10% mucous). Secretes mixed saliva. Has serous demilunes around mucous acini. 3) Sublingual: Predominantly mucous (70% mucous, 30% serous). Secretes viscous, mucin-rich saliva. Stains light with H&E.; Clinical: Mucoepidermoid carcinoma is most common in parotid. Pleomorphic adenoma is most common benign tumor in all three, but most frequent in parotid. Adenoid cystic carcinoma has predilection for submandibular and minor glands.

Jaw and Face Anatomy - Part 19

Neck Triangles & Cervical Plexus - 500 Questions

Topic: Anterior Triangle

Q1. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q2. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q3. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q4. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q5. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q6. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q7. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q8. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q9. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q10. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q11. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q12. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q13. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q14. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q15. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q16. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q17. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q18. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q19. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q20. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q21. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q22. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q23. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q24. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q25. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q26. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q27. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q28. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q29. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q30. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q31. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of

sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q32. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q33. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q34. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q35. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q36. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q37. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q38. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q39. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q40. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q41. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q42. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q43. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q44. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q45. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q46. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q47. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q48. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q49. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q50. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q51. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q52. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q53. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q54. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q55. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q56. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q57. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q58. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q59. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q60. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q61. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q62. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q63. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q64. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q65. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q66. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q67. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q68. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q69. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q70. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q71. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q72. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q73. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q74. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q75. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q76. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q77. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q78. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q79. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q80. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q81. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q82. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q83. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q84. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q85. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q86. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q87. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q88. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q89. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q90. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q91. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q92. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q93. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q94. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q95. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q96. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q97. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q98. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q99. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q100. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q101. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q102. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q103. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q104. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q105. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q106. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q107. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q108. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q109. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q110. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q111. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q112. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q113. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q114. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q115. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q116. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q117. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q118. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q119. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q120. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q121. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q122. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q123. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q124. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q125. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q126. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q127. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q128. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q129. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q130. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q131. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q132. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q133. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q134. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q135. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q136. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q137. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q138. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q139. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q140. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q141. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q142. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q143. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q144. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q145. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q146. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q147. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q148. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q149. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q150. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q151. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q152. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q153. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q154. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q155. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q156. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q157. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q158. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q159. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q160. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q161. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q162. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q163. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q164. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q165. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q166. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q167. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q168. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q169. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q170. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q171. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q172. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q173. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q174. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q175. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q176. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q177. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q178. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q179. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q180. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q181. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q182. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q183. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q184. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q185. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q186. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q187. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q188. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q189. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q190. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q191. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q192. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q193. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q194. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q195. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q196. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q197. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q198. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q199. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q200. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q201. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q202. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q203. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q204. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q205. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q206. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q207. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q208. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q209. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q210. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q211. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q212. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q213. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q214. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q215. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q216. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q217. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q218. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q219. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q220. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q221. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q222. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q223. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q224. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q225. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q226. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q227. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q228. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q229. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q230. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q231. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q232. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q233. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q234. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q235. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q236. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q237. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q238. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q239. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q240. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q241. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q242. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q243. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q244. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q245. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q246. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q247. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q248. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q249. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q250. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q251. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q252. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q253. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q254. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q255. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q256. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q257. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q258. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q259. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q260. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q261. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q262. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q263. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q264. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q265. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q266. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q267. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q268. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q269. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q270. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q271. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q272. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q273. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q274. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q275. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q276. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q277. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q278. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q279. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q280. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q281. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q282. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q283. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q284. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q285. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q286. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q287. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q288. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q289. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q290. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q291. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q292. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q293. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q294. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q295. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q296. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q297. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q298. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q299. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q300. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q301. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q302. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q303. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q304. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q305. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q306. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q307. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q308. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q309. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q310. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q311. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q312. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q313. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q314. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q315. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q316. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q317. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q318. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q319. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q320. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q321. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q322. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q323. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q324. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q325. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q326. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q327. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q328. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q329. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q330. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q331. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q332. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q333. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q334. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q335. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q336. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q337. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q338. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q339. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q340. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q341. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q342. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q343. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q344. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q345. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q346. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q347. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q348. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q349. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q350. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q351. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q352. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q353. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q354. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q355. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q356. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q357. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q358. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q359. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q360. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q361. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q362. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q363. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q364. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q365. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q366. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q367. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q368. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q369. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q370. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q371. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q372. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q373. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q374. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q375. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q376. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q377. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q378. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q379. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q380. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q381. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q382. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q383. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q384. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q385. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q386. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q387. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q388. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q389. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q390. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q391. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q392. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q393. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q394. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q395. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q396. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q397. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q398. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q399. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q400. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q401. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q402. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q403. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q404. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q405. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q406. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q407. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q408. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q409. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q410. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q411. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q412. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q413. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q414. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q415. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q416. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q417. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q418. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q419. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q420. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q421. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q422. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q423. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q424. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q425. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q426. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q427. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q428. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q429. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q430. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q431. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q432. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q433. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q434. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q435. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q436. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q437. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q438. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q439. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q440. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q441. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q442. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q443. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q444. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q445. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q446. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q447. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q448. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q449. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q450. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q451. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q452. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q453. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q454. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q455. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q456. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q457. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q458. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q459. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q460. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q461. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q462. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs

superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q463. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q464. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q465. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q466. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial

plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q467. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q468. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q469. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q470. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid,

trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q471. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q472. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q473. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q474. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q475. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q476. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q477. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q478. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q479. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q480. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q481. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q482. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q483. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q484. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q485. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q486. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q487. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q488. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q489. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q490. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Topic: Anterior Triangle

Q491. What are the boundaries of the anterior triangle of the neck? How is it subdivided?

Answer: Anterior triangle boundaries: Anteriorly - midline of neck; Posteriorly - anterior border of sternocleidomastoid; Superiorly - inferior border of mandible; Apex - jugular notch of sternum. Roof: Skin, superficial fascia with platysma, investing layer of deep cervical fascia. Floor: Pharynx, larynx, thyroid. Subdivisions (4): 1) Submental - single, unpaired. 2) Submandibular (digastric) - paired. 3) Carotid - paired. 4) Muscular (omotracheal) - paired. Clinical: This triangle contains vital structures like carotid arteries, internal jugular vein, cranial nerves IX-XII, and thyroid gland.

Topic: Submandibular Triangle

Q492. Describe the submandibular triangle: boundaries, roof, floor, and contents. What is the clinical significance of the marginal mandibular nerve here?

Answer: Submandibular triangle (digastric triangle) boundaries: Superiorly - inferior border of mandible; Anteroinferiorly - anterior belly of digastric; Posteroinferiorly - posterior belly of digastric. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Mylohyoid and hyoglossus muscles. Contents: Submandibular gland and lymph nodes, submental artery, facial artery and vein, hypoglossal nerve (CN XII), nerve to mylohyoid, and lower pole of parotid. Clinical significance: The marginal mandibular branch of CN VII runs superficial to the facial artery and vein, 1-2cm below the mandible. It is at risk during submandibular gland excision, causing ipsilateral lip paralysis.

Topic: Carotid Triangle

Q493. Describe the carotid triangle: boundaries and major contents. What is the significance of the carotid sheath?

Answer: Carotid triangle boundaries: Superiorly - posterior belly of digastric and stylohyoid; Anteroinferiorly - superior belly of omohyoid; Posteriorly - anterior border of sternocleidomastoid. Floor: Thyrohyoid, hyoglossus, middle and inferior constrictors. Major contents: Common carotid artery bifurcation into internal and external carotid at C3-C4 level, internal jugular vein, vagus nerve (CN X) within the carotid sheath, hypoglossal nerve (CN XII) crossing both carotids, ansa cervicalis on sheath, external carotid branches, and superior

laryngeal nerve. Carotid sheath significance: Encloses the major neurovascular bundle. Infection can spread along it to mediastinum.

Topic: Muscular Triangle

Q494. What are the boundaries and contents of the muscular (omotracheal) triangle? Which glands are found here?

Answer: Muscular (omotracheal) triangle boundaries: Superiorly - superior belly of omohyoid; Anteromedially - midline; Posteroinferiorly - anterior border of sternocleidomastoid. Floor: Sternohyoid and sternothyroid muscles. Contents: Infrahyoid (strap) muscles, thyroid gland, parathyroid glands, trachea, esophagus, recurrent laryngeal nerve in tracheoesophageal groove, and inferior thyroid vessels. Clinical: This is the main surgical approach to thyroidectomy. The recurrent laryngeal nerve is at risk - damage causes hoarseness if unilateral, airway obstruction if bilateral. The external branch of superior laryngeal nerve runs with superior thyroid artery and supplies cricothyroid.

Topic: Posterior Triangle

Q495. What are the boundaries of the posterior triangle of the neck? How is it divided into occipital and supraclavicular triangles?

Answer: Posterior triangle boundaries: Anteriorly - posterior border of sternocleidomastoid; Posteriorly - anterior border of trapezius; Inferiorly - middle third of clavicle; Apex - superior nuchal line. Roof: Skin, superficial fascia, platysma, investing layer of deep fascia. Floor: Prevertebral fascia over splenius, levator scapulae, and scalene muscles. Divided by inferior belly of omohyoid into: 1) Occipital triangle - superior, larger. 2) Supraclavicular (subclavian) triangle - inferior, smaller. Clinical: The external jugular vein crosses the triangle superficially and is used for central line access.

Topic: Posterior Triangle Contents

Q496. Describe the contents of the posterior triangle. What major nerves and vessels are at risk during lymph node biopsy?

Answer: Contents of posterior triangle: 1) Spinal accessory nerve (CN XI): Crosses from sternocleidomastoid to trapezius, 1cm above clavicle. Most important structure at risk during lymph node biopsy - damage causes trapezius paralysis and shoulder drop. 2) Cervical plexus branches: Transverse cervical, supraclavicular, lesser occipital, great auricular. 3) Brachial plexus trunks: Superior and middle trunks in supraclavicular triangle. 4) Subclavian artery (3rd part) and subclavian vein. 5) External jugular vein. 6) Lymph nodes: Level V. Clinical: Biopsies should be done above the omohyoid to avoid CN XI. Subclavian vein puncture is done in the supraclavicular triangle.

Topic: Cervical Plexus

Q497. What is the cervical plexus? Name the cutaneous branches and their area of supply.

Answer: Cervical plexus: Formed by ventral rami of C1-C4. Located deep to sternocleidomastoid, anterior to scalenus medius and levator scapulae. Cutaneous branches (all emerge at Erb's point - midpoint of posterior border of SCM): 1) Lesser occipital (C2): Scalp behind ear. 2) Great auricular (C2-C3): Skin over parotid, auricle, and mastoid. 3) Transverse

cervical (C2-C3): Anterior neck skin. 4) Supraclavicular (C3-C4): Skin over shoulder and upper chest. Motor branches: Ansa cervicalis to strap muscles, phrenic nerve (C3-C5) to diaphragm, and direct branches to scalenes, levator scapulae. Clinical: Cervical plexus block anesthetizes the neck for surgery.

Topic: Ansa Cervicalis

Q498. What is the ansa cervicalis? Name its superior and inferior roots and what muscles does it supply?

Answer: Ansa cervicalis: A nerve loop in the carotid sheath that supplies the infrahyoid (strap) muscles. Superior root (descendens hypoglossi): C1 fibers that traveled with CN XII, leave it in the carotid triangle. Inferior root (descendens cervicalis): C2-C3 fibers. The loop forms on the anterior wall of the carotid sheath. Muscles supplied: Sternohyoid, sternothyroid, and omohyoid. The thyrohyoid and geniohyoid are supplied by C1 fibers via CN XII directly, not by the ansa. Clinical: The ansa is identified and preserved during neck dissection. Damage causes weak neck flexion and impaired swallowing.

Topic: Phrenic Nerve

Q499. What is the phrenic nerve? Describe its origin, course in the neck, and clinical significance.

Answer: Phrenic nerve: Origin - C3, C4, C5 ventral rami ('C3, 4, 5 keep the diaphragm alive'). Course: Forms at upper lateral border of scalenus anterior, runs vertically down on its anterior surface deep to prevertebral fascia. Enters thorax between subclavian artery and vein, anterior to internal thoracic artery. Supplies: Motor to diaphragm, sensory to mediastinal pleura, pericardium, and central diaphragmatic peritoneum. Clinical significance: 1) Injury during neck surgery or interscalene block causes hemidiaphragm paralysis and respiratory distress. 2) Irritation of diaphragmatic peritoneum (e.g., gallbladder disease) causes referred pain to shoulder (C3-C5 dermatomes).

Topic: Deep Cervical Fascia

Q500. Describe the deep cervical fascia and its three layers. What is the carotid sheath and what does it contain?

Answer: Deep cervical fascia has three layers: 1) Investing layer: Most superficial, encloses SCM and trapezius, forms roof of neck triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, and infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column and deep neck muscles. Carotid sheath: Tubular condensation of all three layers that encloses: Internal jugular vein (lateral), common/internal carotid artery (medial), and vagus nerve (posterior between artery and vein). The ansa cervicalis is embedded in its anterior wall. Sympathetic trunk lies posterior to the sheath on prevertebral fascia. Clinical: The carotid sheath is a conduit for spread of infection from neck to mediastinum.

Jaw and Face Anatomy - Part 20 FINAL

High-Yield Review: 500 Mixed Questions from All Systems

Topic: UMN vs LMN

Q1. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q2. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q3. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q4. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q5. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q6. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q7. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q8. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q9. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q10. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q11. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q12. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q13. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q14. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q15. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q16. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q17. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q18. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q19. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q20. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q21. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q22. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q23. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q24. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q25. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q26. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q27. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q28. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q29. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion →

synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q30. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q31. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q32. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q33. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which

normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q34. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q35. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q36. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q37. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q38. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q39. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q40. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q41. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q42. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q43. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q44. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q45. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury

causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q46. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q47. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q48. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q49. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi

prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q50. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q51. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q52. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q53. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q54. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q55. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q56. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q57. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q58. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q59. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q60. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q61. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q62. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q63. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q64. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q65. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q66. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q67. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q68. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q69. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q70. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q71. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q72. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q73. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q74. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q75. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q76. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q77. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q78. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q79. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q80. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q81. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q82. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q83. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q84. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q85. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q86. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q87. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the

cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q88. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q89. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q90. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q91. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at

risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q92. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q93. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q94. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q95. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords

are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q96. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q97. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q98. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q99. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud

sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q100. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q101. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q102. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q103. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q104. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q105. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q106. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q107. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q108. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q109. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion →

synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q110. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q111. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q112. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q113. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which

normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q114. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q115. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q116. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q117. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q118. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q119. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q120. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q121. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q122. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q123. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q124. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q125. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury

causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q126. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q127. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q128. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q129. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi

prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q130. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q131. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q132. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q133. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most

commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q134. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q135. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q136. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q137. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion.

Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q138. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q139. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q140. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q141. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the

forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q142. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q143. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q144. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q145. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q146. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q147. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q148. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q149. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q150. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q151. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q152. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q153. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q154. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q155. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q156. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q157. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q158. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q159. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q160. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q161. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q162. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q163. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q164. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q165. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q166. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q167. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q168. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q169. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q170. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q171. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q172. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q173. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q174. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q175. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q176. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q177. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q178. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q179. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q180. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q181. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q182. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q183. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q184. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q185. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q186. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q187. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the

cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q188. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q189. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q190. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q191. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at

risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q192. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q193. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q194. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q195. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords

are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q196. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q197. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q198. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q199. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud

sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q200. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q201. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q202. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q203. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q204. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q205. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q206. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q207. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q208. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q209. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion →

synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q210. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q211. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q212. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q213. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which

normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q214. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q215. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q216. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q217. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q218. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q219. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q220. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q221. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q222. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q223. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q224. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q225. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury

causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q226. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q227. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q228. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q229. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi

prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q230. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q231. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q232. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q233. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most

commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q234. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q235. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q236. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q237. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion.

Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q238. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q239. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q240. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q241. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the

forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q242. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q243. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q244. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q245. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q246. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q247. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q248. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q249. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q250. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q251. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q252. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q253. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q254. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q255. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q256. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q257. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q258. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q259. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q260. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q261. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q262. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q263. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q264. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q265. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q266. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q267. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q268. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q269. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q270. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q271. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q272. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q273. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q274. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q275. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q276. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q277. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q278. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q279. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q280. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Topic: UMN vs LMN

Q281. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q282. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q283. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q284. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q285. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q286. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q287. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the

cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q288. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q289. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q290. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q291. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at

risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q292. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q293. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q294. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q295. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords

are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q296. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q297. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q298. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q299. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud

sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q300. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q301. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q302. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q303. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q304. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q305. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q306. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q307. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q308. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q309. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion →

synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q310. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q311. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q312. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q313. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which

normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q314. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q315. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q316. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q317. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q318. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q319. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q320. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q321. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q322. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q323. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q324. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q325. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury

causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q326. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q327. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q328. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q329. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi

prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q330. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q331. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q332. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q333. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most

commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q334. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q335. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q336. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q337. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion.

Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q338. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q339. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q340. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q341. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the

forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q342. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q343. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q344. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q345. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q346. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q347. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q348. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q349. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q350. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q351. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q352. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q353. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q354. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q355. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q356. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q357. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q358. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q359. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q360. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q361. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q362. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q363. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q364. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q365. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q366. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q367. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q368. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q369. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q370. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q371. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q372. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q373. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q374. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q375. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q376. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q377. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q378. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q379. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q380. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q381. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q382. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q383. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q384. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q385. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q386. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q387. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the

cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q388. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q389. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q390. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q391. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at

risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q392. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q393. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q394. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q395. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords

are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q396. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q397. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q398. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q399. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud

sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q400. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q401. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q402. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q403. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q404. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q405. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q406. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q407. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q408. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q409. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion →

synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q410. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q411. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q412. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q413. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which

normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q414. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q415. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q416. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q417. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q418. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q419. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q420. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q421. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q422. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q423. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q424. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q425. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury

causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q426. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q427. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q428. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q429. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi

prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q430. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q431. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q432. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q433. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most

commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q434. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q435. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q436. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q437. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion.

Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q438. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q439. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q440. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q441. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the

forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q442. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q443. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q444. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q445. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q446. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q447. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q448. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q449. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q450. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q451. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q452. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q453. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q454. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q455. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q456. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q457. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q458. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q459. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q460. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q461. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q462. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q463. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q464. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q465. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q466. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q467. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q468. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q469. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q470. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q471. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q472. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q473. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q474. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q475. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q476. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q477. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q478. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q479. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q480. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Topic: UMN vs LMN

Q481. A patient has facial paralysis sparing the forehead. Is this an LMN or UMN lesion? Explain the anatomical basis.

Answer: This is an Upper Motor Neuron (UMN) lesion, e.g., stroke. Anatomical basis: The facial motor nucleus has dual cortical input: The part supplying the upper face (frontalis, orbicularis oculi) receives bilateral corticobulbar fibers from both cerebral hemispheres. The part supplying the lower face receives only contralateral input. In UMN lesions, the contralateral cortex is damaged, but the ipsilateral cortex still supplies the upper face, so the forehead is spared. In LMN lesions like Bell's palsy, the final common pathway is destroyed, so all ipsilateral muscles are paralyzed.

Topic: Danger Zone Face

Q482. What is the 'danger zone' of the face? Explain the pathway of infection from a furuncle here to cavernous sinus thrombosis.

Answer: The danger zone is the triangle from the corners of the mouth to the bridge of the nose. Pathway: Infection → facial vein (valveless) → angular vein → superior ophthalmic vein → cavernous sinus. Alternative: Facial vein → deep facial vein → pterygoid venous plexus → emissary veins → cavernous sinus. Clinical: Cavernous sinus thrombosis causes CN III, IV, V1, V2, VI palsies, proptosis, chemosis, and can lead to meningitis or death. This is why squeezing pimples in this area is dangerous.

Topic: IAN Block Complications

Q483. During an inferior alveolar nerve block, the needle is inserted too far posteriorly. What structure may be punctured and what is the clinical sign?

Answer: The pterygoid venous plexus may be punctured. Clinical sign: Immediate hematoma formation with rapid swelling in the infratemporal fossa, causing trismus and pain. The plexus is valveless and communicates with the cavernous sinus, so infection can spread. Also, the inferior alveolar artery can be punctured causing bleeding. Prevention: Do not insert needle more than 25mm, and aspirate before injecting. The medial pterygoid muscle may also be injected causing trismus.

Topic: Lateral Pterygoid

Q484. A patient cannot protrude the mandible and the jaw deviates to the right on opening. Which muscle is paralyzed and which nerve is affected?

Answer: Left lateral pterygoid muscle is paralyzed. Nerve: Mandibular division of trigeminal (V3), specifically the nerve to lateral pterygoid. Explanation: Lateral pterygoid protrudes the mandible. When it contracts unilaterally, it pulls the condyle forward and medially, causing the mandible to deviate to the opposite side. So paralysis of left lateral pterygoid means the right one pulls unopposed, causing deviation to the left (weak side) on opening. The jaw also cannot protrude fully because protrusion requires bilateral contraction.

Topic: Submandibular Triangle

Q485. What are the boundaries of the submandibular triangle? Which branch of CN VII is most at risk during submandibular gland excision?

Answer: Submandibular triangle boundaries: Superiorly - mandible; Anteroinferiorly - anterior digastric; Posteroinferiorly - posterior digastric. Marginal mandibular branch of CN VII is most at risk: It runs superficial to the facial artery and vein, 1-2cm below the inferior border of mandible. It supplies depressor anguli oris, depressor labii inferioris, and mentalis. Injury causes ipsilateral lip droop, inability to depress lower lip, dribbling, and asymmetrical smile. It has no cross-innervation, unlike buccal and zygomatic branches. Surgeons stay 2cm below mandible or identify the nerve.

Topic: Mental Nerve Injury

Q486. A patient has numbness of the lower lip and chin after mandibular third molar extraction. Which nerve was likely injured and where?

Answer: Inferior alveolar nerve was likely injured, specifically the mental nerve branch. Location of injury: In the mandibular canal near the third molar root, or at the mental foramen during flap reflection. The mental nerve supplies general sensation to the lower lip, chin, and labial gingiva of mandibular anteriors. It does not carry taste or motor fibers. Clinical: Numbness is usually temporary (neuropraxia) but can be permanent if the nerve is transected. The incidence is 0.5-5% for third molar extractions. The lingual nerve (taste + sensation to tongue) is also at risk.

Topic: Frey's Syndrome

Q487. What is Frey's syndrome? Explain the anatomical basis involving the otic ganglion and auriculotemporal nerve.

Answer: Frey's syndrome (gustatory sweating) is sweating and flushing of parotid skin during eating. Mechanism: After parotidectomy, postganglionic parasympathetic fibers from the otic ganglion (intended for parotid) are cut. During regeneration, they aberrantly grow into the

cutaneous branches of the auriculotemporal nerve that supply sweat glands. When parasympathetic is activated for salivation, it instead causes sweating. Ganglion: Otic ganglion. Test: Minor's starch-iodine. Treatment: Botox. The auriculotemporal nerve carries both secretomotor fibers to parotid and sensory fibers to skin.

Topic: Trismus

Q488. A patient presents with trismus after an inferior alveolar nerve block. Which muscle is most likely in spasm and why?

Answer: Medial pterygoid muscle is most likely in spasm. Why: It is located in the pterygomandibular space, directly medial to the ramus where the IAN block is given. The needle passes near or through the muscle. Irritation from the needle, hematoma, or injection of solution into the muscle causes spasm. The medial pterygoid elevates and closes the mandible, so spasm causes trismus. It also attaches near the pharynx, so swallowing is painful. Treatment: Heat, NSAIDs, muscle relaxants, physiotherapy. Resolves in 3-6 days.

Topic: Lacrimal Pathway

Q489. Describe the pathway of parasympathetic innervation to the lacrimal gland. Why does Bell's palsy cause dry eye?

Answer: Pathway to lacrimal gland: Superior salivatory nucleus → CN VII → geniculate ganglion → greater petrosal nerve → nerve of pterygoid canal → pterygopalatine ganglion → synapse → orbital branches → zygomatic nerve (V2) → zygomaticotemporal → communicating branch → lacrimal nerve (V1) → lacrimal gland. Why Bell's palsy causes dry eye: The lesion is at or proximal to the geniculate ganglion, interrupting the preganglionic parasympathetic fibers in the greater petrosal nerve. Also, paralysis of orbicularis oculi prevents blinking and tear distribution.

Topic: Ludwig's Angina

Q490. What is Ludwig's angina? Which spaces are involved and why is it a surgical emergency?

Answer: Ludwig's angina is a severe, life-threatening cellulitis of the floor of mouth. Spaces involved: Bilateral submandibular, sublingual, and submental spaces. It begins in the submandibular space (usually from infected mandibular molar) and spreads to sublingual space via the posterior free border of mylohyoid. Why emergency: 1) The tongue and floor of mouth are elevated and pushed posteriorly, causing airway obstruction. 2) Edema spreads rapidly through fascial planes. 3) Can descend into mediastinum along carotid sheath. Signs: Trismus, drooling, 'woody' hard submental swelling, stridor. Treatment: Immediate airway management (intubation/tracheostomy), IV antibiotics, surgical drainage.

Topic: Chorda Tympani

Q491. A patient has loss of taste on anterior 2/3 of tongue and dry mouth after middle ear surgery. Which nerve was damaged?

Answer: Chorda tympani was damaged. Functions: 1) Taste from anterior 2/3 of tongue via special sensory fibers with cell bodies in geniculate ganglion. 2) Preganglionic parasympathetic to submandibular ganglion for submandibular and sublingual glands. Location of damage: In the middle ear where it runs between malleus and incus, medial to tympanic membrane. It is at

risk during tympanoplasty or mastoidectomy. Clinical: Loss of taste on ipsilateral anterior tongue and xerostomia. The chorda tympani joins the lingual nerve, so damage also occurs during third molar surgery.

Topic: Cervical Fascia

Q492. What are the three layers of the deep cervical fascia? What does the carotid sheath contain?

Answer: Three layers of deep cervical fascia: 1) Investing layer: Most superficial, surrounds SCM and trapezius, forms roof of triangles. 2) Pretracheal layer: Encloses thyroid, trachea, esophagus, infrahyoid muscles. 3) Prevertebral layer: Encloses vertebral column, deep muscles, scalene muscles. Carotid sheath contains: Internal jugular vein (lateral), common/internal carotid artery (medial), vagus nerve (posterior between them). Ansa cervicalis is embedded in anterior wall. Sympathetic trunk is posterior to sheath. Clinical: The sheath allows infection to track from neck to mediastinum.

Topic: Thyroglossal Cyst

Q493. A patient has a midline neck swelling that moves with swallowing and tongue protrusion. What is the most likely diagnosis?

Answer: Thyroglossal duct cyst. Embryology: The thyroid develops from the foramen cecum at the tongue base and descends to the neck, leaving a tract - the thyroglossal duct - which normally obliterates. A cyst is a remnant of this duct. Why it moves with tongue protrusion: The duct is attached to the hyoid bone and foramen cecum. Tongue protrusion moves the hyoid and pulls the cyst superiorly. Why it moves with swallowing: The thyroid and hyoid move during swallowing. Location: Midline, anywhere from foramen cecum to suprasternal notch, most commonly below hyoid. Treatment: Sistrunk procedure removing cyst, tract, and central hyoid.

Topic: Pterygomandibular Raphe

Q494. What is the clinical significance of the pterygomandibular raphe? Which muscles attach to it?

Answer: Pterygomandibular raphe: A tendinous band from the hamulus of the medial pterygoid plate to the posterior end of the mylohyoid line of the mandible. Muscles attached: Anteriorly - buccinator (from raphe to orbicularis oris). Posteriorly - superior constrictor (from raphe to pharyngeal tubercle). Clinical significance: 1) It is the landmark for IAN blocks - the needle is inserted lateral to the raphe. 2) It separates the buccal space from the pterygomandibular space. 3) Infections can spread along it. 4) Squamous cell carcinoma can spread submucosally along it from oropharynx to cheek.

Topic: RLN Injury

Q495. A patient has hoarseness after thyroidectomy. Which nerve was likely injured and what is its course?

Answer: Recurrent laryngeal nerve was likely injured. Course: Branch of vagus (CN X). Left RLN loops under arch of aorta and ascends in tracheoesophageal groove to larynx. Right RLN loops under subclavian artery. It supplies all intrinsic laryngeal muscles except cricothyroid. Clinical: Unilateral injury causes hoarseness due to ipsilateral vocal cord paralysis in paramedian position. Bilateral injury causes airway obstruction and stridor because both cords

are paralyzed in paramedian position, requiring tracheostomy. The external branch of superior laryngeal nerve (to cricothyroid) can also be injured, causing inability to tense vocal cord and loss of high pitch.

Topic: Cleft Embryology

Q496. What is the difference between cleft lip and cleft palate embryologically? Why is cleft lip always lateral to the philtrum?

Answer: Cleft lip: Failure of fusion between medial nasal prominence (forms philtrum and premaxilla) and maxillary prominence (forms lateral upper lip). The cleft is always lateral to the philtrum because the philtrum is intact medial nasal tissue. Cleft palate: Failure of fusion of palatal shelves. Primary palate cleft (anterior to incisive foramen) always accompanies cleft lip. Secondary palate cleft (posterior to incisive foramen) can be isolated and is midline. Embryology: Medial nasal prominences fuse in midline at week 6-7. Palatal shelves elevate and fuse at week 8-12. Cleft lip occurs earlier than isolated cleft palate.

Topic: LMN Facial Palsy

Q497. A patient cannot close their eye and cannot wrinkle their forehead on one side. Food collects in the cheek on that side. Name the nerve and site of lesion.

Answer: Facial nerve (CN VII), lower motor neuron lesion at or distal to the stylomastoid foramen. Evidence: 1) Cannot wrinkle forehead = frontalis paralyzed (temporal branch). 2) Cannot close eye = orbicularis oculi paralyzed (temporal/zygomatic branches). 3) Food collects in cheek = buccinator paralyzed (buccal branch). All branches affected means lesion is proximal to pes anserinus, i.e., Bell's palsy. If forehead was spared, it would be UMN lesion. Site: Most commonly in the labyrinthine segment of facial canal due to edema from HSV-1 reactivation. Complete paralysis of all ipsilateral facial muscles = LMN.

Topic: Palate Blood Supply

Q498. What is the blood supply to the hard palate? Which foramen transmits the greater palatine artery?

Answer: Blood supply to hard palate: Greater palatine artery (from maxillary artery) enters via greater palatine foramen, runs anteriorly in a groove to supply the hard palate and gingiva. It anastomoses with the nasopalatine artery (from sphenopalatine) which exits the incisive foramen. The greater palatine foramen is located medial to the maxillary second or third molar, halfway between gingival margin and midline. Clinical: Greater palatine nerve block is done here for palatal anesthesia. The artery can cause profuse bleeding during palatal surgery. Pressure is applied for hemostasis.

Topic: Hyperacusis

Q499. A patient has hyperacusis after Bell's palsy. Which muscle is paralyzed and what is the anatomical explanation?

Answer: Stapedius muscle is paralyzed. Anatomical explanation: The nerve to stapedius branches from CN VII in the mastoid segment, before the chorda tympani and before the nerve exits the stylomastoid foramen. In Bell's palsy, the lesion is typically in the labyrinthine segment, proximal to the stapedius branch. Stapedius dampens stapes vibrations to loud

sounds. Paralysis removes this dampening, causing hyperacusis - painful sensitivity to loud noise. Clinical: Hyperacusis is absent if the lesion is at the stylomastoid foramen (distal to stapedius branch). This localizes the lesion. The stapedial reflex is lost.

Topic: CN XI Injury

Q500. What are the boundaries of the posterior triangle? Which nerve is most at risk during lymph node biopsy here and what is the deficit?

Answer: Posterior triangle boundaries: Anterior - posterior border of SCM; Posterior - anterior border of trapezius; Inferior - middle third of clavicle. Most at risk nerve: Spinal accessory nerve (CN XI). Course: Exits skull via jugular foramen, passes through SCM, emerges at midpoint of posterior border, crosses the triangle 1cm above clavicle to enter trapezius. Deficit: Trapezius paralysis causes shoulder drop, inability to shrug shoulder, weakness of overhead abduction, and winging of scapula. Clinical: This is the most common iatrogenic nerve injury in the neck. Lymph node biopsies should be done above the omohyoid or with careful identification of CN XI.

Head & Neck Anatomy

Complete Course - 20 Lessons + Resources

Compiled: April 22, 2026

1. Course Outline - All 20 Lessons

Download each lesson as a separate PDF:

#	Lesson Title	Key Topics
01	Blood Supply of Brain	Circle of Willis, ICA, Vertebral, Stroke syndromes
02	Cranial Venous Sinuses	Dural sinuses, Cavernous sinus, Thrombosis
03	Circle of Willis	6 arteries, Aneurysms, Variations, Imaging
04	Facial Nerve + Parotid	CN VII course, Branches, Bell's palsy, Parotid gland
05	Trigeminal V1, V2, V3	Ophthalmic, Maxillary, Mandibular divisions
06	Trigeminal Neuralgia	Pathophysiology, MVD, Gamma knife
07	Salivary Glands + PPF	Parotid, Submandibular, Sublingual, PPF
08	Fascial Spaces + ITF	Infratemporal fossa, Spaces, Infections
09	Maxillary Sinus + Venous Drainage	Sinus anatomy, Pterygoid plexus, Danger triangle
10	Deep Cervical Fascia + Neck Triangles	Fascia layers, Triangles, Carotid sheath
11	Pharynx + Palate	3 parts pharynx, Muscles, CN IX-X, Gag reflex
12	Larynx + RLN	9 cartilages, Vocal cords, CN X, Vocal cord palsy
13	Cervical Plexus + Neck Dissection	C1-C4, Ansa, Phrenic, Levels I-VI
14	Orbital Anatomy + EOM	7 bones orbit, 6 EOM, CN III-IV-VI, Visual pathway
15	Ear + Vestibulocochlear	External/Middle/Inner ear, CN VIII, Rinne/Weber
16	Cranial Nerves Summary I-XII	Exit foramina, Tests, Lesions, Syndromes
17	Autonomic Head & Neck	4 Parasymp ganglia, Sympathetic chain, Horner's
18	Embryology - Pharyngeal Arches	5 arches, Pouches, Clefts, DiGeorge, Treacher Collins
19	Clinical Case Integration	8 cases: Cavernous sinus, Thyroidectomy, Ludwig, etc
20	Final Review - High-Yield Tables	All mnemonics, Danger zones, Exam checklist

3. Primary Reference Sources

This course was synthesized from standard medical textbooks and curricula:

• **1. Gray's Anatomy for Students, 4th Edition** - Drake, Vogl, Mitchell. Elsevier. Chapters: Head & Neck.

• **2. Clinically Oriented Anatomy, 8th Edition** - Moore, Dalley, Agur. Wolters Kluwer. Head & Neck sections.

• **3. Netter's Atlas of Human Anatomy, 7th Edition** - Netter. Elsevier. Plates: Head & Neck, Nervous System.

• **4. Neuroanatomy Through Clinical Cases, 2nd Edition** - Blumenfeld. Sinauer. Brainstem, Cranial Nerves.

• **5. Langman's Medical Embryology, 14th Edition** - Sadler. Wolters Kluwer. Chapter 17: Head & Neck.

• **6. Grant's Dissector, 17th Edition** - Tank. Wolters Kluwer. Head & Neck dissection guides.

• **7. Essential Clinical Anatomy, 5th Edition** - Moore, Agur. Wolters Kluwer. Clinical correlations.

• **8. High-Yield Neuroanatomy, 5th Edition** - Fix. LWW. Cranial nerves, Stroke syndromes.

• **9. USMLE First Aid 2024** - Le, Bhushan. McGraw Hill. High-yield facts, mnemonics.

• **10. BRS Gross Anatomy, 9th Edition** - Chung, Chung. LWW. Board review questions.

4. Question Bank Topics Covered

The following high-yield topics and clinical scenarios were integrated into the lessons:

• Stroke syndromes: ACA, MCA, PCA, Basilar, PICA, AICA territories

• Cavernous sinus syndrome: CN III, IV, V1, V2, VI palsies + thrombosis

• Bell's palsy vs Stroke: LMN vs UMN facial weakness

• Trigeminal neuralgia: V2/V3 distribution, MVD surgery

• Parotidectomy complications: CN VII injury, Frey's syndrome

• Thyroidectomy complications: RLN palsy, SLN palsy, Hypocalcemia

• Ludwig's angina: Submandibular space infection, Airway

• Orbital blowout fracture: Inferior rectus entrapment, Diplopia

• CN III palsy: Down and out, Ptosis, Dilated pupil

• CN IV palsy: Head tilt, Diplopia on stairs

• CN VI palsy: Esotropia, False localizing sign

• Horner's syndrome: Ptosis, Miosis, Anhidrosis, Pancoast

• Jugular foramen syndrome: CN IX, X, XI deficits

• DiGeorge syndrome: 22q11, Thymus, Parathyroid, Cardiac

• Rinne & Weber tests: Conductive vs Sensorineural hearing loss

• Meniere's disease: Vertigo, Tinnitus, Hearing loss triad

• Danger triangle of face: Infection → Cavernous sinus

• Killian's dehiscence: Zenker diverticulum

• Lamina papyracea: Orbital cellulitis from ethmoiditis

• Berry ligament: RLN danger in thyroidectomy

5. How to Use This Course

1. Read lessons 1-20 in order for systematic learning.
2. Use Lesson 16 for cranial nerve quick review before exams.
3. Use Lesson 19 for case-based learning and clinical integration.
4. Use Lesson 20 for last-minute high-yield review.
5. Cross-reference tables and mnemonics in each lesson.
6. Correlate anatomy with clinical cases in Lesson 19.

End of Course Resource List

Good luck with your studies!
